A Switched LQ Regulator Design in Continuous Time

Pierre Riedinger

Abstract—In this technical note, the design of a LQ regulator for linear switched systems in continuous time is investigated. From a relaxation of the optimal control problem, a Lyapunov based switching law is provided. Even if the subsystems are all unstable, the state feedback switching law can be applied subject to a positiveness condition. In any cases, the real cost is always upper bounded by the Lyapunov function value. The optimality of the switching law is also discussed and we prove that the switching conditions are optimal in some generic cases. This point explains why the obtained results over examples approach finely the optimal solutions. Finally, a design strategy is also given that extends the results to the cases where the subsystems are controlled linear systems.

Index Terms—LQ regulator, optimal control, switched systems.

I. INTRODUCTION

In the last decade, many contributions have addressed the design of stabilizing switching laws for switched systems both in continuous and discrete time (see for examples [1]–[4] for dynamic programming approaches, [5]–[7] for variational approaches, and [8]–[10] for Lyapunov based approaches). This problem cannot be considered trivial even numerically [7], [11] and the goal to design closed loop control, based on the optimization of a criteria, is a challenging task.

LQ regulators play a central role in the control theory of linear systems due to their simple design to meet performance requirements and their robustness properties. Up to now, the exact solution of a switched LQ problem is not available. Only approximations of the state feedback switching law have been proposed in the literature using the dynamic programming [1]–[4]. The practical obstacle to the application of these methods relies on the difficulties to compute numerically a good approximation of the solution not only for small dimensional problems. Alternatively, open loop control can be achieved using direct or indirect optimization methods [6], [7] but singular solutions [5], [12] entail numerical difficulties [11].

In [10], Lyapunov based approaches are developed for a mode independent quadratic cost and the authors show that the design conditions are not convex and the problem cannot be solved by Linear Matrix Inequality (LMI) tools. A switched quadratic Lyapunov approach is also proposed in [8], based on Lyapunov-Metzler inequalities. If some LMI conditions can be guaranteed, the method allows to define a state feedback switching law and can be applied even when subsystems are unstable. An upper bound on the cost is also provided but the optimality of the proposed stabilizing switching law is not evaluated.

In this technical note, a variational approach has been used to analyze the optimal necessary conditions occurring in the switched LQ problem. A first result yields the right expression of the optimal cost with respect to the state and the co-state. From this analysis, a control Lyapunov function as well as a state feedback switching law is determined.

An important point which is discussed, is that the obtained switching conditions are actually optimal in some generic cases when the optimal control is constant. This explains why the state feedback switching law leads to some appealing results close to the optimal. In any case, the value of Lyapunov function defines an upper bound on the real cost and gives a guarantee on performances.

These results are established in a relaxed framework for which the singular arcs [5], [12] that appear in the optimal solution, are properly taken into account. This is a key point since for this class of systems, the optimal solutions are frequently singular as indicating by the big quantity of randomly tested examples.

The technical note is organized as follows. Section II is dedicated to the problem formulation and to the necessary conditions that must be fulfilled to solve the optimal control problem. A preliminary result establishes the right expression of the optimal cost when the optimal switching law is said regular. In Section III, the main result of this technical note is given. A control Lyapunov function and an ad hoc switching law are determined. In Section IV, we discuss the optimality of the proposed switching law. In Section V, several examples illustrate that the proposed switching law is effectively optimal. We propose also a design strategy in the case where the subsystems are, eventually all non stabilizable, controlled linear systems.

II. PROBLEM FORMULATION AND PRELIMINARY RESULTS

We consider the class of linear switched systems in continuous time

\[ \dot{x}(t) = A_{σ(t)}x(t), \quad x(0) = x_0 \]  

(1)

where \( σ : [0, +∞) \rightarrow S = \{1, \ldots, s\} \) denotes the switching law that selects the active mode at time \( t \) by choosing among a finite collection of matrices \( A_i \in \mathbb{R}^{n \times n}, i \in S \). Our aim is to design a state feedback switching law (i.e., \( x \rightarrow σ(x) \)) for system (1) that approaches the optimal solution of the following optimization problem:

\[ \min_{σ, u} \frac{1}{2} \int_0^\infty x^T(t)Q_{σ(t)}x(t) + u^T(t)R_{σ(t)}u(t)\,dt \]  

(2)

where \( Q_i = Q_i^T > 0, i \in S \) subject to \( \dot{x}(t) = A_{σ(t)}x(t), x(0) = x_0 \).

A usual framework [5], [11] to solve optimal control problem for switched systems \( (\dot{x} = f_i(x), i \in S) \) is to solve its relaxed version, replacing the vector field set \( \{f_i(x)\} \) by its convex hull \( (\dot{x} = \text{co}\{f_i(x)\}) \). At least, three reasons justify the convexification of the problem: (i) the solutions are well defined (Filippov; [13]); (ii) the density of the switched system trajectories into the trajectories of its relaxed version [14]; (iii) the existence of singular optimal solutions are taken into account [5], [12].

The relaxed version of Problem 1 is then given as a pure continuous time optimal control problem consisting of replacing the matrices \( Q_i \) and \( A_i \) respectively by their convex combination i.e., \( Q(λ(t)) = \sum_{i=1}^s λ_i(t)Q_i \) and \( A(λ(t)) = \sum_{i=1}^s λ_i(t)A_i \) where \( λ(t) \in Λ = \{λ \in \mathbb{R}^s : \sum_{i=1}^s λ_i = 1, \; λ_i \geq 0\} \) plays the role of the control variable.

Manuscript received January 17, 2013; revised May 15, 2013; accepted October 17, 2013. Date of publication November 06, 2013; date of current version April 18, 2014. This work was supported by the European Community’s Seventh Framework Programme (FP7/2007-2013) under grant agreement n°257462 and by HYCON2 Network of Excellence “Highly-Complex and Networked Control Systems”. Recommended by Associate Editor H.L. Trentelman.

The technical note is organized as follows. Section II is dedicated to the problem formulation and to the necessary conditions that must be fulfilled to solve the optimal control problem. A preliminary result establishes the right expression of the optimal cost when the optimal switching law is said regular. In Section III, the main result of this technical note is given. A control Lyapunov function and an ad hoc switching law are determined. In Section IV, we discuss the optimality of the proposed switching law. In Section V, several examples illustrate that the proposed switching law is effectively optimal. We propose also a design strategy in the case where the subsystems are, eventually all non stabilizable, controlled linear systems.

To apply Pontryagin Maximum Principle (PMP) for Problem 1 or its relaxed version, the Hamiltonian function is defined as follows:

\[ \mathcal{H}(x, \lambda^*, p) = \sum_{i=1}^{n} \lambda_i \mathcal{H}_i(x, p) \]  

(3)

with \( \mathcal{H}_i(x, p) = p_i^T A_i x + \frac{1}{2} x^T Q_i x \) and where \( p \) defines the co-state. This leads to the following classical necessary conditions for optimality [15]:

**Theorem 1:** Suppose that \( \lambda^* \) is optimal with the corresponding state \( x^* \). Then, there exists an absolutely continuous function \( p^* \), named co-state, such that:

1. \( p^*_i \neq 0 \)
2. \( p^* = \sum_{i=1}^{n} \lambda^*_i(t) (-A_i^T p_i^* - Q_i x^*) \) for almost all \( t \in \mathbb{R}^+ \)
3. \( \lambda^*_i(t) = \text{arg min}_{\lambda_i \in \Lambda} \mathcal{H}_i(x^*(t), \lambda_i, p^*(t)) \)
4. \( \dot{\lambda}^*_i(t) = p^*_i(t) \)

From Item 3 and (3), it is clear that if there exists \( i \in S \) at time \( t \) such that \( \lambda_i^*(t) = 0 \), then the optimal control has to satisfy \( \lambda_i^*(t) = 1 \) and \( \lambda_j^*(t) = 0 \), \( \forall j \in S \setminus \{i\} \). Therefore, we can derive the necessary condition for optimality, namely a singular control \( \lambda \) exists, for which \( \dot{\lambda}_i = 0 \) or \( \lambda^*_i = 1 \), \( \forall k \in S \setminus \{i\} \) on a non empty time interval \((a, b)\). This is a well known situation in the literature [16]–[18] and second order necessary conditions given by the Generalized Legendre-Clebsh Condition [19], [20] are generally necessary to solve the optimal control problem.

**Definition 1:** A singular control \( \lambda_i \) is such that there exist at least two indices \( i, j \), for which \( \lambda_i = \lambda_j = 0 \) on a semi zero measure time interval \((a, b)\) and satisfying \( \lambda(t) \in \Lambda \). Moreover, \( \lambda_i \) is a potential candidate for optimality. Moreover, a so called singular control \( \lambda \) exist, for which \( \lambda(t) \in \Lambda \), \( \forall k \in S \setminus \{i\} \) on a non empty time interval \((a, b)\). This is a well known situation in the literature [16]–[18] and second order necessary conditions given by the Generalized Legendre-Clebsh Condition [19], [20] are generally necessary to solve the optimal control problem.

**Remark 1:** A singular control defines a Filippov solution [21] for the original switched system (1). Hence, it allows to extend properly the notion of optimal solution for switched systems. Roughly speaking, when an optimal solution of the relaxed problem possesses singular arcs, these arcs define sliding surfaces for the switched system (1) which lead to chattering if the surface is attractive. It is noteworthy that only suboptimal solutions can be achieved for the switched systems due to the limited switching frequency; see for example [5].

**Theorem 2:** If \( p^*(0) \) is an optimal value for the state at a given \( x_0 \), then \( p^*(0) \) is an optimal value for the initial state \( x_0 \) to all \( \eta \). Moreover, the optimal cost \( V^* \) is homogeneous of degree 2:

\[ V^*(\eta x_0) = \eta^2 V^*(x_0) \]

**Proof:** First, observe by linearity that applying the same control \( \lambda \) to two initial positions \( x_0 \) and \( x_0+\eta \) that the resulting trajectories are homogeneous of degree one i.e., \( x(t, \eta x_0) = \eta x(t, x_0) \). It follows that the associated cost \( V(x, \lambda) := \frac{1}{2} \int_0^T x^T(t) Q x(t) dt \) are also given by : \( V(\eta x_0, x_0, \lambda) = \eta^2 V(x_0, x_0, \lambda) \). It is obvious that if \( \lambda^* \) is an optimal control for initial state \( x_0 \), then it is also an optimal one for the initial position \( \eta x_0 \) (easy to show by contradiction). It remains to show that if \( p^*(0) \) is an optimal value for the state at a given initial position \( x_0 \), then \( V^*(0) \) is for \( x_0 \). This is achieved if the two corresponding control laws are the same. Due to the homogeneity of \( (x, p) \), the switching condition \( \lambda^*(t) = \text{arg min}_{\lambda \in \Lambda} \mathcal{H}(x^*(t), \lambda, p^*(t)) \) is not modified when we integrate the Hamiltonian system from \((x_0, p(0))\) or from \((\eta x_0, \eta p(0))\).

**Remark 2:** If the value function \( V^* \) is homogeneous with degree two then its gradient is also homogeneous with degree one (at points where it can be defined).

**Theorem 3:** Assuming that Problem 1 admits a solution for each \( x_0 \), then the value function \( V^*(x_c) \) is continuous.

**Proof:** It can be achieved using the fact that for given control \( \lambda \in \Lambda \) and a given \( B > 0 \), \( A(\lambda)x \) is clearly Lipschitz on any ball \( B(0, R) \) as well as \( x^T Q(x) \). Then, an adapted proof and inspired by \([22, \text{chap. 8 pp. } 188-189]\) can be applied to get the result.

**Remark 3:** Unfortunately, we fail to prove that \( V^* \) is also Lipschitz and then differentiable almost everywhere (which is the case for the optimal control problem states in finite time).

Now, consider the set of Lyapunov equations corresponding to each subsystem \((A_i), i \in S\) for which a symmetric solution \( P_i \) exists and is unique

\[ A_i^T P_i + P_i A_i + Q_i = 0 \]

(4)

Let us define the variables \( p_i \) from the co-state \( p \) as

\[ p_i = p_i + (P_i - P_i) x \]

(5)

then, the Hamiltonian function \( H_i \) can be simplified to

\[ H_i = \sum_{i=1}^{n} \lambda_i \mathcal{H}_i \]  

where \( \lambda_i = 0 \) or \( \lambda_i \neq 0 \) \( \forall k \in S \setminus \{i\} \). Therefore, we can derive the necessary condition for optimality, namely a singular control \( \lambda \) exists, for which \( \lambda(t) \in \Lambda \), \( \forall k \in S \setminus \{i\} \) on a non empty time interval \((a, b)\). This is a well known situation in the literature [16]–[18] and second order necessary conditions given by the Generalized Legendre-Clebsh Condition [19], [20] are generally necessary to solve the optimal control problem.

**Theorem 4:** Assume there exists a non singular stabilizing control \( \lambda \) and a co-state \( p \) such that Theorem 1 is satisfied. Denote by \( \{t_0, t_1, \ldots, t_N\} \) with \( t_0 = 0 \), the associated switching time sequence (possibly infinite) and by \( \{t_0, t_1, \ldots, t_N\} \) the corresponding mode sequence. Then, the cost function is determined by

\[ V(x_c, \lambda) = \frac{1}{2} \sum_{k=0}^{N} P_{x_k} x_0 + p_{t_k}(0)^2 x_c - L \]

(11)

where \( L = \exp_{x_0} \mathcal{N} P_{x_k} x_0 \) and \( N \in \mathbb{N} \cup \{+\infty\} \) the number of switchings. If the trajectory is optimal, \( L = 0 \) and the co-state \( p_{t_k}(t) \) for \( t_0 \leq t \leq t_1 \) can be identified with

\[ p_{t_k}(t) = \sum_{k=1}^{N} \Pi(t, t_k) (P_{t_k} - P_{t_{k-1}}) x_k \]

(12)

where \( \Pi(t, t_k) \) is the transition function from time \( t \) to \( t_k \).
Proof: As it is assumed that the switching sequence is non singular, the cost function can be written
\[
V(x_c, \lambda) = \frac{1}{2} \int_0^t x^T Q_i x dt + \frac{1}{2} \int_t^\infty x^T Q_i x dt + \cdots
\]
Using (4) and integrating, we get
\[
V(x_c, \lambda) = \frac{1}{2} x^T \bar{P}_0 \bar{x}_0 + \frac{1}{2} \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k
\]
where \(x_k := x(t_k)\) is the state at switching times \(t_k, k = \{0, \ldots, N\}\).
Define \(G := \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k\). Using (7), \(G\) can be written as
\[
G = \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k = x^T_1 p_{i1}(t_1) - p_{i1}(t_1) + x^T_2 p_{i1}(t_2) + \cdots
\]
where \(x_k := x(t_k)\) is the state at switching times \(t_k, k = \{0, \ldots, N\}\).
Define \(G := \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k\). Using (7), \(G\) can be written as
\[
G = \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k = x^T_1 p_{i1}(t_1) - p_{i1}(t_1) + x^T_2 p_{i1}(t_2) + \cdots
\]
where \(x_k := x(t_k)\) is the state at switching times \(t_k, k = \{0, \ldots, N\}\).
Define \(G := \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k\). Using (7), \(G\) can be written as
\[
G = \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k = x^T_1 p_{i1}(t_1) - p_{i1}(t_1) + x^T_2 p_{i1}(t_2) + \cdots
\]
where \(x_k := x(t_k)\) is the state at switching times \(t_k, k = \{0, \ldots, N\}\).
Define \(G := \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k\). Using (7), \(G\) can be written as
\[
G = \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k = x^T_1 p_{i1}(t_1) - p_{i1}(t_1) + x^T_2 p_{i1}(t_2) + \cdots
\]
where \(x_k := x(t_k)\) is the state at switching times \(t_k, k = \{0, \ldots, N\}\).
Define \(G := \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k\). Using (7), \(G\) can be written as
\[
G = \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k = x^T_1 p_{i1}(t_1) - p_{i1}(t_1) + x^T_2 p_{i1}(t_2) + \cdots
\]
where \(x_k := x(t_k)\) is the state at switching times \(t_k, k = \{0, \ldots, N\}\).
Define \(G := \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k\). Using (7), \(G\) can be written as
\[
G = \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k = x^T_1 p_{i1}(t_1) - p_{i1}(t_1) + x^T_2 p_{i1}(t_2) + \cdots
\]
where \(x_k := x(t_k)\) is the state at switching times \(t_k, k = \{0, \ldots, N\}\).
Define \(G := \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k\). Using (7), \(G\) can be written as
\[
G = \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k = x^T_1 p_{i1}(t_1) - p_{i1}(t_1) + x^T_2 p_{i1}(t_2) + \cdots
\]
where \(x_k := x(t_k)\) is the state at switching times \(t_k, k = \{0, \ldots, N\}\).
Define \(G := \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k\). Using (7), \(G\) can be written as
\[
G = \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k = x^T_1 p_{i1}(t_1) - p_{i1}(t_1) + x^T_2 p_{i1}(t_2) + \cdots
\]
where \(x_k := x(t_k)\) is the state at switching times \(t_k, k = \{0, \ldots, N\}\).
Define \(G := \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k\). Using (7), \(G\) can be written as
\[
G = \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k = x^T_1 p_{i1}(t_1) - p_{i1}(t_1) + x^T_2 p_{i1}(t_2) + \cdots
\]
where \(x_k := x(t_k)\) is the state at switching times \(t_k, k = \{0, \ldots, N\}\).
Define \(G := \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k\). Using (7), \(G\) can be written as
\[
G = \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k = x^T_1 p_{i1}(t_1) - p_{i1}(t_1) + x^T_2 p_{i1}(t_2) + \cdots
\]
where \(x_k := x(t_k)\) is the state at switching times \(t_k, k = \{0, \ldots, N\}\).
Define \(G := \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k\). Using (7), \(G\) can be written as
\[
G = \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k = x^T_1 p_{i1}(t_1) - p_{i1}(t_1) + x^T_2 p_{i1}(t_2) + \cdots
\]
where \(x_k := x(t_k)\) is the state at switching times \(t_k, k = \{0, \ldots, N\}\).
Define \(G := \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k\). Using (7), \(G\) can be written as
\[
G = \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k = x^T_1 p_{i1}(t_1) - p_{i1}(t_1) + x^T_2 p_{i1}(t_2) + \cdots
\]
where \(x_k := x(t_k)\) is the state at switching times \(t_k, k = \{0, \ldots, N\}\).
Define \(G := \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k\). Using (7), \(G\) can be written as
\[
G = \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k = x^T_1 p_{i1}(t_1) - p_{i1}(t_1) + x^T_2 p_{i1}(t_2) + \cdots
\]
where \(x_k := x(t_k)\) is the state at switching times \(t_k, k = \{0, \ldots, N\}\).
Define \(G := \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k\). Using (7), \(G\) can be written as
\[
G = \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k = x^T_1 p_{i1}(t_1) - p_{i1}(t_1) + x^T_2 p_{i1}(t_2) + \cdots
\]
where \(x_k := x(t_k)\) is the state at switching times \(t_k, k = \{0, \ldots, N\}\).
Define \(G := \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k\). Using (7), \(G\) can be written as
\[
G = \sum_{k=1}^N x^T_k (P_{ik} - P_{ik-1}) x_k = x^T_1 p_{i1}(t_1) - p_{i1}(t_1) + x^T_2 p_{i1}(t_2) + \cdots
\]
for any fixed $x$, the minimum exists and $\inf_{x \in \Lambda^+(M)} x^T P_3 x = \min_{x \in \Lambda^+(M)} x^T P_3 x$.

Moreover, the family of function indexed by $\lambda \in \Lambda^+(M)$ and defined by $x \rightarrow x^T P_3 x$ is uniformly locally Lipschitz on any ball $B([0, R])$ with a Lipschitz constant equals to $K := 2MR$. This is obvious since for all $\lambda \in \Lambda^+(M)$

$$\alpha_{\min}(\lambda) \cdot |x|^2 \leq \inf_{x \in \Lambda^+(M)} x^T P_3 x < x^T P_3 x \leq M|\lambda|^2.$$  \hfill (21)

So, as any $x^T P_3 x$ have a Lipschitz constant equals to $K$ on a ball of radius $R$, we can conclude that it is also the case for the minimum. Indeed, for any pair $(x, y) \in B([0, R])$, there exists a pair $(\lambda_1, \lambda_2) \in \Lambda^+(M)^2$ such that

$$\inf_{x \in \Lambda^+(M)} x^T P_3 x = \min_{x \in \Lambda^+(M)} x^T P_3 x = |x||y||\lambda_1^T P_3 \lambda_2|.$$  \hfill (22)

Thus, by continuity, there exists $z$ on the line segment $[x, y]$ such that $x^T P_3 z = \lambda_1^T P_3 \lambda_2$ and it follows:

$$|V_{\min}(x) - V_{\min}(y)| \leq |x^T P_3 x - z^T P_3 z| + |z^T P_3 z - y^T P_3 y| \leq K|x - z| + K|z - y|.$$  \hfill (23)

The min type function $V_{\min}$ is also proper in view of the left part of inequality \hfill (21).

**Definition 3:** Let us define $I(x)$ as the set of values $\lambda \in \Lambda^+(M)$ where the minimum $V_{\min}(x)$ is achieved and $I(x)$ as the set of indices where the minimum over $\lambda \in \Lambda^+(M)$ is reached

$$I(x) := \arg \min_{i \in S} x^T (P_3 - P_i) A_i x.$$  \hfill (25)

The following lemma is useful latter in order to define an appropriate descent direction for $V_{\min}$.

**Lemma 1:** For every $\lambda \in \Lambda$, such that (18) admits a solution, $\min_{i \in S} x^T (P_3 - P_i) A_i x$ is non positive.

Proof: For a given $\lambda \in \Lambda^+$, left-multiplying by $x^T$ and right-multiplying by $x$ the (18) and using $Q(\lambda) = \sum_{i \in S} \lambda_i Q_i$ and $A_i^T P_3 + P_3 A_i + Q_i = 0$, we get

$$\sum_{i \in S} \lambda_i x^T (P_3 - P_i) A_i x = 0.$$  \hfill (26)

So, we cannot have $x^T (P_3 - P_i) A_i x > 0$ for every $i \in S$ because in this case the left-hand member of equality \hfill (26) would be positive.

We can now state one of the main result of this technical note:

**Theorem 6:** Assume there exists at least a $\lambda \in \Lambda$ such that $A(\lambda)$ is Hurwitz. Then, the state feedback switching rule defined by

$$i^*(x) \in I(x) = \arg \min_{i \in S} x^T (P_3 - P_i) A_i x.$$  \hfill (27)

stabilizes the switching system (1) with a cost smaller than $\frac{1}{2} V_{\min}(x_0)$.

Proof: Let $\lambda \in \Lambda$ such that $A(\lambda)$ is Hurwitz, then the Lyapunov equation (18) admits a unique solution $P_3 > 0$. The matrix $A_i^*(\lambda) = A(\lambda) + P_3 A_i$ is still Hurwitz if $\lambda^*$ belongs to a sufficiently small neighborhood of $\lambda$ and so (18) admits a unique solution for every $\lambda^*$ in some neighborhood of $\lambda$. Thus, the interior of $\Lambda^*$ is non empty and $V_{\min}$ is well defined.

Let us now consider the directional derivative of $V_{\min}(x(t))$ with respect to $\dot{x} = A(\nu) x$, $\nu \in \Lambda$ as

$$V'_{\min}(x; \nu) = \lim_{h \rightarrow 0} \frac{V_{\min}(x + hA(\nu)x) - V_{\min}(x)}{h}.$$  \hfill (28)

Denote by $g(\lambda) := x^T P_3 x$ the continuous function defined on $\Lambda^+(M) \times \mathbb{R}^n$. Then, as the following conditions are met: 1. the set $\Lambda^+(M)$ is compact, 2. for each $\lambda \in \Lambda^+(M)$, the directional derivative $g(\lambda)(x; \nu)$ exists, 3. $\forall \nu \in \mathbb{R}^n$, $\forall \lambda \in \Lambda^+(M)$, $g(\lambda)(x; \nu) \rightarrow g(\lambda)(x; \nu)$ uniformly in $\lambda$ as $h \rightarrow 0$, it can be concluded (from Theorem 6.1, [23, p. 350–353])

$$V_{\min}(x(t); \nu) = \min_{\lambda \in I(x)} x^T P_3 A(\nu)x.$$  \hfill (29)

Taking $\nu = i^*(x) \in I(x)$, it follows using Lemma 1 that:

$$V'_{\min}(x, i^*(x)) = \min_{\lambda \in I(x)} 2x^T P_3 A_i i^*(x) x \leq -2x^T Q_i i^*(x) x < 0,$$

$$x \neq 0.$$  \hfill (30)

Therefore, for any initial condition $x_0$

$$V_{\min}(x(t)) + \int_0^T x^T (\nu - i^*(x)) Q_i i^*(x) x dt \leq V_{\min}(x_0), \quad \forall t \geq 0.$$  \hfill (31)

As $Q_i > 0$, $\forall i \in S$ and as $V_{\min}(\cdot)$ is proper, it follows that:

$$V_{\min}(x(t)) \rightarrow 0 \text{ and } x(t) \rightarrow 0 \text{ when } t \rightarrow +\infty.$$  \hfill (32)

**IV. DISCUSSION CONCERNING THE SWITCHING LAW AND ITS OPTIMALITY**

In this part we want to discuss the degree of optimality of the provided switching law. Observe first that in the case where all matrices $A_i$ are Hurwitz, then the matrices $P_i$ are definite positive for each mode and the Lyapunov function $V_{\min}$ satisfies always the following inequality: $V_{\min}(x) \leq \min_{i \in S} x^T P_i x$. One can also observe that for a given initial state $x$, the value $\frac{1}{2} V_{\min}(x)$ is the best cost related to every constant convex combination that stabilizes the relaxed system. As we will see, this is an important point if a singular control occurs in the solution.

Now, in the general case, when can we say that $\frac{1}{2} V_{\min}(x)$ is optimal? The answer is: "Along the part of trajectories where the optimal control $\lambda^*$ is constant to reach the origin."

In order to prove this last sentence, consider an optimal solution and assume that the optimal control is piecewise smooth with a countable number of discontinuities occurring at time $t_1$, $t_2$, $\ldots$. Then, on time interval $(t_k, t_{k+1})$, the optimal control $\lambda^*$ is smooth and we can denote by $\tilde{\lambda} (t_i) = A(\lambda^*(t))$, $\tilde{Q}(t_i) = Q(\lambda^*(t))$, the time varying matrices. The co-state $\rho(t)$ can be identified as for a time varying linear system to

$$\dot{\tilde{P}}(t) = \tilde{P}(t) \tilde{A}(t) + \tilde{Q}(t) \quad (30)$$

As it is mandatory that the hamiltonian $\mathcal{H} = y^T \tilde{A} x + \frac{1}{2} x^T \tilde{Q} x$ remains equal to zero, it implies that along the optimal trajectory: $x^T \dot{\tilde{P}} x = 0$. Thus, $\mathcal{H}$ can be rewritten as in the case of (26) as follows:

$$\mathcal{H} = \sum_{i \in S} \lambda_i x^T (\tilde{P} - P_i) A_i x = 0.$$  \hfill (31)
where the optimal control $\lambda^*$ satisfies the complementarity constraint

$$0 < \lambda^*_i \perp x^T (\bar{P} - P_i) A_i x > 0, \ i \in S. \ (x \perp y \ means \ xy = 0). \ (32)$$

**Theorem 7:** If after a given time instant $t$, the optimal control $\lambda^*$ stays constant on $(t, +\infty)$ and if $P_i > 0$ then the switching law provided by Theorem 6 coincides with the optimal one.

**Proof:** This is obvious since as in the classical LQ problem and after the last switch, the matrix $\lambda^*$ stands for the constant optimal control (eventually singular). Thus, as it is assumed that $P_i > 0$, by optimality, $x^T P_{\lambda^*} x = \min_{\lambda \in A} x^T P_\lambda x$ and it can be concluded that $\lambda^* \in L(x)$. Along the optimal trajectory, the optimal switching condition is now based on the minimization of $x^T (P_{\lambda^*} - P_i) A_i x, i \in S$ which is exactly the switching condition provided by the switching rule of Theorem 6. The resulting trajectories are then the same if $\lambda^*$ is admissible for the switched system. Else a chattering motion occurs around the sliding surface defined by conditions (32) and the trajectory can be considered to be similar of the optimal one provided that the switching frequency is sufficiently high [5].

**Remark 5:** Theorem 7 applies at least for two important generic cases: when the switching sequence is finite, and, in dimension 2, along the singular arcs which are necessarily defined by lines passing through the origin and by a constant control [12].

Formally, we can justified the design of $V_{min}$ as follow. Assuming known the value function, one can write for any $T > 0$, $V^*(x_0) =$ \min_{\lambda \in L(x)} \int_0^T x^T(t) Q \, x(t) + V^*(x(T)) dt$. The transversality condition of PMP implies at time $T$, $p^*(T) = \frac{\partial V^*(x(T))}{\partial x}$. Now suppose that $V^*(x(T))$ is approximated by $V_{min}(x(T))$ (if exists). Then, an approximation of $p^*(x(T))$ is given by $p_{\lambda}(x(T)) \approx P_{\lambda} x(T)$ with $\lambda \in L(x)$. Thus, it is easy to check that the minimization of the Hamiltonian at time $T$ leads to the switching law (27). As the problem is homogenous and if the approximation is "good", one can infer that $p^*(x) \approx P_{\lambda^*} x$ with $\lambda^* \in L(x)$ for every $x$. Roughly speaking, the switching law (27) matches the optimal one when $P_{\lambda^*} x$ is a good approximation of $p^*$.

V. ILLUSTRATIVE EXAMPLES

Before presenting some examples, it is important to mention that it is not necessary to ensure a stabilizing switched law to determine all the possible values of the set $\Lambda^+ \{ M \}$. Only one value is sufficient to guarantee the stability. So, a reasonable finite number of values ensures performances. A possibility to get this finite number is to discretize the set $\Lambda$.

**A. Example 1 : A Regular Case**

In [24], we have proposed a periodic solution that approximated the optimal one for a switched system defined by two modes. The matrices corresponding to this example are

$$A_1 = \begin{pmatrix} -1.89 & 4.29 \\ -2.41 & -1.77 \end{pmatrix}, \ A_2 = \begin{pmatrix} -1.14 & 0.95 \\ -1.23 & -1.57 \end{pmatrix},$$

$$Q_1 = \begin{pmatrix} 0.99 & -0.18 \\ -0.18 & 4.59 \end{pmatrix}, \ Q_2 = \begin{pmatrix} 2.15 & 0.66 \\ 0.66 & 1.53 \end{pmatrix}. $$

For this example, there is no singular arc and the solution is always regular (and, thus, admissible for the switched system). Fig. 1 shows the state space trajectories for the switching law given by (27) and the optimal one. The later is obtained by NL programming in a suitable formulation taking into account singular arcs [11]. If not, numerical difficulties in the control determination are often encountered. We can see that the two solutions match well together. Thus, even if no argument has been advanced in this case, it seems that the provided switching conditions are close to the optimal.

Fig. 2 compares the optimal cost with the costs obtained by using the switching law, only mode 1 and only mode 2, respectively. This comparison is made for initial states taken on the unit ball, the x-axis represent the angle $\theta$. It can be observed that the cost associated to the switching law coincides the cost of the optimal numerical solution. Of course, the essential difference is that the numerical solution is an open loop control while the switching law defines a closed loop control.

**B. Example 2 : A Singular Case**

Let us take an example (chosen randomly) for which singular arcs occur in the solutions. The matrices for this example are

$$A_1 = \begin{pmatrix} -0.96 & -9.93 \\ 0.68 & -5.68 \end{pmatrix}, \ A_2 = \begin{pmatrix} -1.10 & 0.95 \\ 1.88 & -2.76 \end{pmatrix}$$

$$Q_1 = \begin{pmatrix} 1.17 & 0.90 \\ 0.90 & 5.60 \end{pmatrix}, \ Q_2 = \begin{pmatrix} 2.11 & -1.07 \\ -1.07 & 2.64 \end{pmatrix}. $$

As shown in Figs. 3 and 4, the result is clearly near optimal. By comparison, a min switching strategy defined by: $i(x) = \begin{cases} 1 \text{ if } x^T Q_1 x + x^T A_1 x < x^T Q_2 x + x^T A_2 x, \\ 2 \text{ otherwise.} \end{cases}$
arg min_{x \in \mathbb{R}^n} \{x^T P x\} leads to a cost given by $\frac{1}{2} \min_{x \in \mathbb{R}^n} \{x^T P x\}$ which is clearly not optimal as the two examples show.

C. Example 3: Extension to Controlled Linear Switched Systems

Consider the controlled linear switched systems in continuous time

$$\dot{x}(t) = A_{\sigma(t)} x(t) + B_{\sigma(t)} u_{\sigma(t)}(t), \quad x(0) = x_0$$

where $\sigma : [0, +\infty) \rightarrow S = \{1, \ldots, s\}$ denotes the switching law that selects the active mode at time $t$ by choosing among a finite collection of controlled linear systems. For $i \in S$, $A_i \in \mathbb{R}^{n \times n}$, $B_i \in \mathbb{R}^{n \times m_i}$, $x(t) \in \mathbb{R}^n$ is the state and $u_i(t) \in \mathbb{R}^{m_i}$ ($m_1 \leq n$) is the control associated to mode $i$.

We assume that the switched system is stabilizable but eventually all the pair $(A_i, B_i)$, $i \in S$ cannot be stabilized.

A direct extension of the proposed switching law consists to solve:

**Problem 2:** Minimize

$$\min_{x_0, u_i} \frac{1}{2} \int_0^\infty x^T(t) \hat{Q}_{\sigma(t)} x(t) + u_i^T(t) \hat{R}_{\sigma(t)} u_i(t) dt$$

subject to $\dot{x}(t) = (A_{\sigma(t)} - B_{\sigma(t)} K_{\sigma(t)}) x(t)$, where $\hat{Q}_i = Q_i + K_i^T R_i K_i$ and matrices $(R_i, Q_i)$ and $K_i$ correspond to an LQ design for the subsystem $(A_i, B_i)$, for all $i \in S$.

Then, a stabilizing switching law can be obtained in two steps: 1.) Define static gain $K_i$ that stabilize the controllable subspace of each subsystems using a LQ design, 2.) Check if the switching law can be applied for Problem 2 i.e., if $\Lambda^* \{ M \}$ is non empty for a sufficiently large $M$.

Let us illustrate our purpose on an example. Consider two non stabilizable subsystems defined by

$$A_2 = \begin{pmatrix} 1 & 0 \\ 0 & -2 \end{pmatrix}, \quad A_1 = \begin{pmatrix} -2 & 0 \\ 0 & 1 \end{pmatrix}, \quad B_2 = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad B_1 = \begin{pmatrix} 1 \\ 0 \end{pmatrix}.$$

Clearly the controllable subspace is generated by the canonical basis vector $[1, 0]^T$ for the first system while it is $[1, 0, 1]^T$ for the second. Thus, following the first step, an LQ design is used on each controllable subspace to determine two static gains $K_1$ and $K_2$ such that $\int_0^\infty x^T(t) Q_i x(t) + u_i^T(t) R_i u_i(t)$ is minimized by $u_i = -K_i x$. We have chosen $R_i = Q_i = 1, i = 1, 2$ then $K_1 = K_2 = 0.2361$. Thus, the switched linear system is now defined by $\dot{x} = (A_i - B_i K_i) x$, $i = 1, 2$.

Fig. 3. Example 2: State space trajectories: (red) optimal (NLP); (blue) switching law.

Fig. 4. Example 2: Cost comparisons for different initial positions taken on the unit ball.

Fig. 5. Example 3: State space trajectories: (red) optimal (NLP); (blue) switching law.

Fig. 6. Example 3: Cost comparisons for different initial positions taken on the unit ball.
The second step consists in applying the switching law with weight matrices $\tilde{Q}_i$. For this example, we have chosen $\tilde{Q}_i = Ia + K_i^2B, K_i$, $i = 1, 2$. The Figs. 5 and 6 show once again that the obtained switching law is optimal by comparison with the numerical solution. It can be noticed that the solutions of (18) for mode 1 and 2 are not positive definite as expected, see Fig. 6.

VI. CONCLUSION

A state feedback switching law based on control Lyapunov function for switched LQ regulator problems in continuous time has been proposed. The stabilizing feedback can be applied even if the subsystems are all unstable. The only condition that is required, is the existence of at least a stable convex combination of the subsystems. Even if the exact optimal solution is not determined, we have shown that the switching conditions involved by the switching law can be optimal. More precisely, this generic situation occurs along arcs (singular or not) ending to the origin with a constant optimal control. As in dimension two, the singular controls are constant, the switching law is really optimal in most of encountered 2-D examples. In any case, a guarantee on the cost is provided by an upper bound given by the value of the Lyapunov function.
