jochen.schmid@mathematik.uni-wuerzburg.de

We establish characterizations of weak input-to-state stability for abstract dynamical systems with inputs, which are similar to characterizations of uniform and of strong input-to-state stability established in a recent paper by A. Mironchenko and F. Wirth. We also answer, by means of suitable counterexamples, two open questions concerning weak input-to-state stability (and its relation to other common stability concepts) raised in the aforementioned paper.

Index terms: Input-to-state stability (weak, strong, uniform), infinite-dimensional dynamical systems with inputs

1 Introduction

In this paper, we study the property of weak input-to-state stability of general dynamical systems $\mathfrak{S} = (X, \mathcal{U}, \varphi)$ with inputs. Such a system is determined by its generally infinite-dimensional state space X , its set \mathcal{U} of admissible input functions, and its dynamical map

$$\varphi : [0, \infty) \times X \times \mathcal{U} \rightarrow X$$

which for given initial state $x_0 \in X$ and input $u \in \mathcal{U}$ yields the state $\varphi(t, x_0, u)$ of the system at any time $t \in [0, \infty)$. Weak input-to-state stability of such a system means, roughly speaking, that 0 is an asymptotically stable – that is, stable and attractive – equilibrium point of the (undisturbed) system with input $u = 0$ and that this asymptotic stability property is affected only slightly by small (disturbance) inputs $u \neq 0$. In precise terms, this means that there are continuous monotonically increasing functions $\underline{\sigma}, \underline{\gamma}, \bar{\gamma} : [0, \infty) \rightarrow [0, \infty)$ with $\underline{\sigma}(0), \underline{\gamma}(0), \bar{\gamma}(0) = 0$ such that for all $(x_0, u) \in X \times \mathcal{U}$ the following estimates hold true:

$$\|\varphi(t, x_0, u)\| \leq \underline{\sigma}(\|x_0\|) + \underline{\gamma}(\|u\|_{\mathcal{U}}) \quad (t \in [0, \infty)) \quad (1.1)$$

and

$$\limsup_{t \rightarrow \infty} \|\varphi(t, x_0, u)\| \leq \bar{\gamma}(\|u\|_{\mathcal{U}}) \quad (1.2)$$

meaning that the stability property and the attractivity property of 0, respectively, are affected only slightly by disturbance inputs $u \in \mathcal{U}$ of small magnitude $\|u\|_{\mathcal{U}}$. Inequality (1.1) is commonly referred to as the uniform global stability and (1.2) is referred to as the weak asymptotic gain property of the system. It should be noted that if the limit relation (1.2) holds uniformly w.r.t. $u \in \mathcal{U}$ or, respectively, locally uniformly w.r.t. $x_0 \in X$ and uniformly w.r.t. $u \in \mathcal{U}$, then the system is even strongly or uniformly input-to-state stable, respectively.

In recent years, these last two notions of strong and especially of uniform input-to-state stability have been intensively studied. See, for instance, [2], [10], [11], [12], [14], [5], [6], [15], [9], [13], [20], [7], [8], [23], [24] and the references therein. Also, weak input-to-state stability can be established for a rather large class of semilinear systems (both in the case of inputs entering in the domain and in the case of inputs entering at the boundary of the domain on which the partial differential equation describing the system lives). See [16], [17], [19]. It is therefore natural to study the property of weak input-to-state stability – and especially its relation to other common stability properties – from a general point of view.

In the present paper, we establish a characterization of weak input-to-state stability similar to the characterizations of strong and uniform input-to-state stability from [12] and, moreover, we investigate the relation of weak input-to-state stability to other common and natural stability concepts, namely strong input-to-state stability and zero-input uniform global stability. In particular, we answer two open questions from [12].

In more detail, the contents of the present paper can be described as follows. Section 2 provides the necessary preliminaries setting out and recalling the precise definitions of abstract dynamical systems with inputs and of the various stability notions employed later on. In Section 3 we establish a characterization of weak input-to-state stability which is parallel to the characterizations of strong and uniform input-to-state stability for infinite-dimensional systems recently established in [12]. In Section 4 we investigate the relation of weak input-to-state stability to strong input-to-state stability. We show, by means of a suitable counterexample, that weak input-to-state stability is strictly weaker than strong input-to-state stability, thereby answering an open question raised in [12]. In our example, we work with modulated-linear systems, which are described by evolution equations of the form

$$x' = \alpha(u(t))Ax \tag{1.3}$$

with a linear operator A and a modulating prefactor $\alpha(u(t))$, and the input space \mathcal{U} is a certain subset of $L^p([0, \infty), \mathbb{R})$. We also show that in the special case of linear systems, weak input-to-state stability is equivalent to strong input-to-state stability. In the case of semilinear systems, the relation of weak and strong input-to-state stability remains open. We show at least, however, that for semilinear systems weak input-to-state stability is strictly weaker than uniform input-to-state stability. In Section 5 we investigate the relation of weak input-to-state stability to the combination of zero-input uniform global stability and the weak asymptotic gain property. We show, by means of a suitable

counterexample, that weak input-to-state stability is strictly stronger than the aforementioned combination of properties, thereby answering an open question raised in [12]. In our example, we work with linear systems with input space \mathcal{U} being a certain subset of $L^\infty([0, \infty), \mathbb{R})$. We also show that for linear systems with input space \mathcal{U} being a full L^p -space, weak input-to-state stability is equivalent to the aforementioned combination of properties.

In the entire paper, $\mathbb{R}_0^+ := [0, \infty)$ denotes the non-negative reals and $\overline{B}_r^Z(0) := \{z \in Z : \|z\| \leq r\}$ for any subset Z of a normed linear space with norm $\|\cdot\|$. As usual, \mathcal{K} and \mathcal{L} denote the following classes of comparison functions:

$$\begin{aligned} \mathcal{K} &:= \{\gamma \in C(\mathbb{R}_0^+, \mathbb{R}_0^+) : \gamma \text{ strictly increasing with } \gamma(0) = 0\} \\ \mathcal{L} &:= \{\gamma \in C(\mathbb{R}_0^+, \mathbb{R}_0^+) : \gamma \text{ strictly decreasing with } \lim_{r \rightarrow \infty} \gamma(r) = 0\}. \end{aligned}$$

Also, $\|\cdot\|_p$ for any $p \in [1, \infty) \cup \{\infty\}$ stands for the standard norm on $L^p(\mathbb{R}_0^+, U)$, where U is any Banach space, and $u_1 \&_\tau u_2$ stands for the concatenation of the functions $u_1, u_2 : \mathbb{R}_0^+ \rightarrow U$ at time $\tau \in \mathbb{R}_0^+$ defined by

$$(u_1 \&_\tau u_2)(t) := \begin{cases} u_1(t) & (t \in [0, \tau)) \\ u_2(t - \tau) & (t \in [\tau, \infty)) \end{cases}.$$

And finally, in the context of admissible control operators – and, in particular, of extrapolation of semigroup generators – we adopt the standard notation from [3], [21].

2 Setting and definitions

2.1 Systems with inputs

We begin by setting out the class of systems that we – just like [12] – are going to deal with in this paper.

Definition 2.1. A (forward-complete) dynamical system $\mathfrak{S} = (X, \mathcal{U}, \varphi)$ with inputs is determined by

- a normed linear space X (the state space of \mathfrak{S}) endowed with a norm $\|\cdot\|_X$
- a non-empty set $\mathcal{U} \subset \{\text{functions } u : \mathbb{R}_0^+ \rightarrow U\}$ (the set of admissible inputs of \mathfrak{S}) endowed with a norm $\|\cdot\|_{\mathcal{U}}$
- a map $\varphi : \mathbb{R}_0^+ \times X \times \mathcal{U} \rightarrow X$ (the dynamical map of \mathfrak{S})

such that the following properties are satisfied:

- (i) \mathcal{U} is invariant under shifts to the left, that is, $u(\cdot + \tau) \in \mathcal{U}$ and $\|u(\cdot + \tau)\|_{\mathcal{U}} \leq \|u\|_{\mathcal{U}}$ for every $u \in \mathcal{U}$ and $\tau \in \mathbb{R}_0^+$
- (ii) \mathcal{U} is invariant under concatenations, that is, $u_1 \&_\tau u_2 \in \mathcal{U}$ for every $u_1, u_2 \in \mathcal{U}$ and $\tau \in \mathbb{R}_0^+$

(iii) $\varphi(0, x_0, u) = x_0$ for every $(x_0, u) \in X \times \mathcal{U}$ and, moreover, φ is cocyclic, that is,

$$\varphi(t + s, x_0, u) = \varphi(t, \varphi(s, x_0, u), u(\cdot + s)) \quad (2.1)$$

for every $(x_0, u) \in X \times \mathcal{U}$ and $s, t \in \mathbb{R}_0^+$

(iv) $\varphi(\cdot, x_0, u) : \mathbb{R}_0^+ \rightarrow X$ is continuous for every $(x_0, u) \in X \times \mathcal{U}$

(v) φ is causal, that is,

$$\varphi(\cdot, x_0, u_1)|_{[0, \tau]} = \varphi(\cdot, x_0, u_2)|_{[0, \tau]} \quad (2.2)$$

for every $x_0 \in X$, $u_1, u_2 \in \mathcal{U}$ and $\tau \in \mathbb{R}_0^+$ with $u_1|_{[0, \tau]} = u_2|_{[0, \tau]}$.

In the following, we will always write $\|\cdot\| := \|\cdot\|_X$ for brevity. Since \mathcal{U} is not assumed to be a linear space, it is slightly abusive to speak of a norm $\|\cdot\|_{\mathcal{U}}$ on \mathcal{U} . What we mean is, of course, that $\|\cdot\|_{\mathcal{U}}$ is the restriction of a norm of some linear space $\mathcal{F} \supset \mathcal{U}$.

2.2 Stability and attractivity concepts

We continue by recalling the stability and attractivity concepts from [12] that will be used in the sequel.

Definition 2.2. A dynamical system $\mathfrak{S} = (X, \mathcal{U}, \varphi)$ with inputs is called

(i) *uniformly globally stable* iff there exist $\underline{\sigma}, \underline{\gamma} \in \mathcal{K}$ such that for all $(x_0, u) \in X \times \mathcal{U}$

$$\|\varphi(t, x_0, u)\| \leq \underline{\sigma}(\|x_0\|) + \underline{\gamma}(\|u\|_{\mathcal{U}}) \quad (t \geq 0) \quad (2.3)$$

(ii) *uniformly locally stable* iff there exist $\underline{\sigma}, \underline{\gamma} \in \mathcal{K}$ and $r > 0$ such that (2.3) holds true for all $(x_0, u) \in \overline{B}_r^X(0) \times \overline{B}_r^{\mathcal{U}}(0)$

(iii) *zero-input uniformly globally stable* or *zero-input uniformly locally stable*, respectively, iff $0 \in \mathcal{U}$ and the restricted system $\mathfrak{S}_0 := (X, \mathcal{U}_0, \varphi)$ with $\mathcal{U}_0 := \{0\}$ is uniformly globally or uniformly locally stable, respectively.

Definition 2.3. Suppose $\mathfrak{S} = (X, \mathcal{U}, \varphi)$ is a dynamical system with inputs and $\overline{\gamma} \in \mathcal{K} \cup \{0\}$. \mathfrak{S} is said to be

(i) of *weak asymptotic gain* $\overline{\gamma}$ iff for every $\varepsilon > 0$ and $(x_0, u) \in X \times \mathcal{U}$ there exists a time $\overline{\tau}(\varepsilon, x_0, u) \in \mathbb{R}_0^+$ such that

$$\|\varphi(t, x_0, u)\| \leq \varepsilon + \overline{\gamma}(\|u\|_{\mathcal{U}}) \quad (t \geq \overline{\tau}(\varepsilon, x_0, u)) \quad (2.4)$$

(ii) of *strong asymptotic gain* $\overline{\gamma}$ iff for every $\varepsilon > 0$ and $x_0 \in X$ there exists a time $\overline{\tau}(\varepsilon, x_0) \in \mathbb{R}_0^+$ such that

$$\|\varphi(t, x_0, u)\| \leq \varepsilon + \overline{\gamma}(\|u\|_{\mathcal{U}}) \quad (t \geq \overline{\tau}(\varepsilon, x_0) \text{ and } u \in \mathcal{U}) \quad (2.5)$$

(iii) of *uniform asymptotic gain* $\bar{\gamma}$ iff for every $\varepsilon > 0$ and $r > 0$ there exists a time $\bar{\tau}(\varepsilon, r) \in \mathbb{R}_0^+$ such that

$$\|\varphi(t, x_0, u)\| \leq \varepsilon + \bar{\gamma}(\|u\|_{\mathcal{U}}) \quad (t \geq \bar{\tau}(\varepsilon, r) \text{ and } (x_0, u) \in \overline{B}_r^X(0) \times \mathcal{U}). \quad (2.6)$$

Also, \mathfrak{S} is said to be of *weak asymptotic gain* iff it is of weak asymptotic gain $\bar{\gamma}$ for some $\bar{\gamma} \in \mathcal{K} \cup \{0\}$.

Definition 2.4. Suppose $\mathfrak{S} = (X, \mathcal{U}, \varphi)$ is a dynamical system with inputs. \mathfrak{S} is said to have the *weak limit property* iff there is a $\bar{\gamma} \in \mathcal{K}$ such that for every $\varepsilon > 0$ and $(x_0, u) \in X \times \mathcal{U}$ there exists a time $\bar{\tau}(\varepsilon, x_0, u)$ such that

$$\inf_{t \in [0, \bar{\tau}(\varepsilon, x_0, u)]} \|\varphi(t, x_0, u)\| \leq \varepsilon + \bar{\gamma}(\|u\|_{\mathcal{U}}). \quad (2.7)$$

In [12], the weak asymptotic gain and the weak limit properties are referred to simply as asymptotic gain and limit property, respectively. We deviate from that terminology in order to emphasize the logical relation to the strong and uniform variants and in order to emphasize the parallelism of certain issues.

Lemma 2.5. *Suppose that $\mathfrak{S} = (X, \mathcal{U}, \varphi)$ is a dynamical system with inputs and that $\mathcal{U} \subset L^p(\mathbb{R}_0^+, U)$ with $\|\cdot\|_{\mathcal{U}} := \|\cdot\|_p$ for some $p \in [1, \infty)$ or that $\mathcal{U} \subset L_0^\infty(\mathbb{R}_0^+, U)$ with $\|\cdot\|_{\mathcal{U}} := \|\cdot\|_\infty$, where U is a Banach space and*

$$L_0^\infty(\mathbb{R}_0^+, U) := \{u \in L^\infty(\mathbb{R}_0^+, U) : \|u(\cdot + t)\|_\infty \rightarrow 0 \text{ as } t \rightarrow \infty\}.$$

If \mathfrak{S} is of weak asymptotic gain, then it is automatically of weak asymptotic gain 0.

Proof. Suppose \mathfrak{S} is of weak asymptotic gain $\bar{\gamma} \in \mathcal{K}$ (with corresponding times $\bar{\tau}(\varepsilon, x_0, u)$) and let $\varepsilon > 0$ and $(x_0, u) \in X \times \mathcal{U}$ be fixed. Since $\|u(\cdot + t)\|_{\mathcal{U}} \rightarrow 0$ as $t \rightarrow \infty$ by our assumptions on \mathcal{U} , we can choose a time $t_0 \in \mathbb{R}_0^+$ such that

$$\bar{\gamma}(\|u(\cdot + t_0)\|_{\mathcal{U}}) \leq \varepsilon. \quad (2.8)$$

Since \mathfrak{S} is of weak asymptotic gain $\bar{\gamma}$, we have for all $s \geq \bar{\tau}(\varepsilon, \varphi(t_0, x_0, u), u(\cdot + t_0))$ that

$$\|\varphi(s + t_0, x_0, u)\| = \|\varphi(s, \varphi(t_0, x_0, u), u(\cdot + t_0))\| \leq \varepsilon + \bar{\gamma}(\|u(\cdot + t_0)\|_{\mathcal{U}}). \quad (2.9)$$

Combining now (2.8) and (2.9) we see that for all

$$t \geq \tau_0(\varepsilon, x_0, u) := t_0 + \bar{\tau}(\varepsilon, \varphi(t_0, x_0, u), u(\cdot + t_0))$$

one has $\|\varphi(t, x_0, u)\| \leq 2\varepsilon$. Consequently, \mathfrak{S} is of weak asymptotic gain 0, as desired. ■

2.3 Input-to-state stability concepts

With the stability and attractivity properties recalled above, we can now define the central concepts of this paper, namely weak, strong, and uniform input-to-state stability.

Definition 2.6. A dynamical system $\mathfrak{S} = (X, \mathcal{U}, \varphi)$ with inputs is called *weakly input-to-state stable*, or *strongly input-to-state stable*, or *uniformly input-to-state stable*, respectively, iff it is uniformly globally stable and of weak, or strong, or uniform asymptotic gain, respectively.

Instead of uniform input-to-state stability one often simply speaks of input-to-state stability in the literature.

3 Characterization of weak input-to-state stability

We begin with a characterization of weak input-to-state stability which is parallel to the recently established characterizations of strong and uniform input-to-state stability from [12]. It should be pointed out that the equivalence of items (i) and (ii) below is already stated in [12] (Remark 5), yet without proof.

Theorem 3.1. *Suppose $\mathfrak{S} = (X, \mathcal{U}, \varphi)$ is a dynamical system with inputs. Then each of the following items is equivalent to \mathfrak{S} being weakly input-to-state stable.*

- (i) \mathfrak{S} is uniformly globally stable and has the weak limit property
- (ii) \mathfrak{S} is uniformly globally stable and has the weak asymptotic gain property
- (iii) there exist $\sigma, \gamma \in \mathcal{K}$ and $\beta : X \times \mathcal{U} \times \mathbb{R}_0^+ \rightarrow \mathbb{R}_0^+$ with $\beta(x_0, u, \cdot) \in \mathcal{L}$ for $x_0 \neq 0$ such that for all $(x_0, u) \in X \times \mathcal{U}$ one has:

$$\|\varphi(t, x_0, u)\| \leq \beta(x_0, u, t) + \gamma(\|u\|_{\mathcal{U}}) \quad (t \in \mathbb{R}_0^+) \quad (3.1)$$

and

$$\beta(x_0, u, t) \leq \sigma(\|x_0\|) \quad (t \in \mathbb{R}_0^+). \quad (3.2)$$

Proof. We first show the implication from (i) to (ii). So assume that (i) is satisfied and let $\underline{\sigma}, \underline{\gamma} \in \mathcal{K}$ and $\bar{\gamma} \in \mathcal{K}$, $\bar{\gamma}(\varepsilon, x_0, u)$ be chosen as in the definitions of uniform global stability and of the weak limit property, respectively. We define the function γ by

$$\gamma(r) := \underline{\sigma}(2\bar{\gamma}(r)) + \underline{\gamma}(r) \quad (r \in \mathbb{R}_0^+) \quad (3.3)$$

which obviously belongs to \mathcal{K} . Choose and fix now $\varepsilon > 0$ and $(x_0, u) \in X \times \mathcal{U}$ and set

$$\tau(\varepsilon, x_0, u) := \bar{\tau}(\delta(\varepsilon), x_0, u) \quad \text{with} \quad \delta(\varepsilon) := \frac{1}{2}\underline{\sigma}^{-1}(\varepsilon). \quad (3.4)$$

Let $t \geq \tau(\varepsilon, x_0, u)$. It then follows by the assumed weak limit property that there exists a $t_0 \in [0, \tau(\varepsilon, x_0, u)]$ such that

$$\|\varphi(t_0, x_0, u)\| \leq \delta(\varepsilon) + \bar{\gamma}(\|u\|_{\mathcal{U}}) \quad (3.5)$$

It further follows by the cocycle property of φ and the assumed uniform global stability that

$$\begin{aligned}\|\varphi(t, x_0, u)\| &= \|\varphi(t - t_0, \varphi(t_0, x_0, u), u(\cdot + t_0))\| \\ &\leq \underline{\sigma}(\|\varphi(t_0, x_0, u)\|) + \underline{\gamma}(\|u(\cdot + t_0)\|).\end{aligned}\quad (3.6)$$

Combining now (3.5) and (3.6) we see for every $t \geq \tau(\varepsilon, x_0, u)$ that

$$\|\varphi(t, x_0, u)\| \leq \underline{\sigma}(\delta(\varepsilon) + \bar{\gamma}(\|u\|_{\mathcal{U}})) + \underline{\gamma}(\|u\|_{\mathcal{U}}) \leq \varepsilon + \gamma(\|u\|_{\mathcal{U}}), \quad (3.7)$$

as desired. In the first inequality of (3.7) we used that $\|u(\cdot + t_0)\| \leq \|u\|_{\mathcal{U}}$ and in the second inequality we used the elementary fact that

$$\underline{\sigma}(a + b) \leq \underline{\sigma}(2 \max\{a, b\}) \leq \underline{\sigma}(2a) + \underline{\sigma}(2b)$$

for all $a, b \in \mathbb{R}_0^+$.

We now show the implication from (ii) to (iii). So assume that (ii) is satisfied and let $\underline{\sigma}, \underline{\gamma} \in \mathcal{K}$ and $\bar{\gamma} \in \mathcal{K}$ be chosen as in the definitions of uniform global stability and of the weak asymptotic gain property, respectively. We define the functions σ, γ by

$$\sigma(r) := 2\underline{\sigma}(r) \quad \text{and} \quad \gamma(r) := \max\{\underline{\gamma}(r), \bar{\gamma}(r)\} \quad (3.8)$$

which obviously belong to \mathcal{K} . What we have to do now is to define for each given $(x_0, u) \in X \times \mathcal{U}$ a function $\beta(x_0, u, \cdot) : \mathbb{R}_0^+ \rightarrow \mathbb{R}_0^+$ in such a way that $\beta(x_0, u, \cdot) \in \mathcal{L}$ for $x_0 \neq 0$ and that (3.1) and (3.2) are satisfied. So let $(x_0, u) \in X \times \mathcal{U}$ be fixed for the rest of the proof (of the implication from (ii) to (iii)) and assume without loss of generality that

$$x_0 \neq 0. \quad (3.9)$$

(If $x_0 = 0$, then $\underline{\sigma}(\|x_0\|) = 0$ and thus by the assumed uniform global stability the desired estimates (3.1) and (3.2) hold true with the choice $\beta(x_0, u, \cdot) := 0$.) In order to construct $\beta(x_0, u, \cdot)$ we distinguish two cases, namely whether or not $\|\varphi(\cdot, x_0, u)\|$ eventually lies below $\gamma(\|u\|_{\mathcal{U}})$, that is, whether or not there exists a $t_0 \in \mathbb{R}_0^+$ such that

$$\|\varphi(t, x_0, u)\| \leq \gamma(\|u\|_{\mathcal{U}}) \quad (t \geq t_0). \quad (3.10)$$

Suppose first that we are in the case where $\|\varphi(\cdot, x_0, u)\|$ eventually lies below $\gamma(\|u\|_{\mathcal{U}})$. In this case, set

$$\beta_0(x_0, u, t) := \underline{\sigma}(\|x_0\|) \chi_{[\tau_0(x_0, u), \tau_\infty(x_0, u))}(t) \quad (t \in \mathbb{R}_0^+), \quad (3.11)$$

where

$$\begin{aligned}\tau_0(x_0, u) &:= 0 \quad \text{and} \quad \tau_\infty(x_0, u) := \max\{\sup M_\infty(x_0, u), 0\} \\ M_\infty(x_0, u) &:= \{t \in \mathbb{R}_0^+ : \|\varphi(t, x_0, u)\| > \gamma(\|u\|_{\mathcal{U}})\}.\end{aligned}$$

In other words, $\tau_\infty(x_0, u)$ is the smallest time t_0 for which (3.10) holds true. In particular, we have

$$0 \leq \tau_\infty(x_0, u) < \infty. \quad (3.12)$$

It follows that $\beta_0(x_0, u, \cdot)$ is a monotonically decreasing step function satisfying

$$\beta_0(x_0, u, t) \longrightarrow 0 \quad (t \rightarrow \infty) \quad (3.13)$$

as well as

$$\|\varphi(t, x_0, u)\| \leq \beta_0(x_0, u, t) + \gamma(\|u\|_{\mathcal{U}}) \quad \text{and} \quad \beta_0(x_0, u, t) \leq \underline{\sigma}(\|x_0\|) \quad (3.14)$$

for all $t \in \mathbb{R}_0^+$. (In order to see (3.14.a) for $t < \tau_\infty(x_0, u)$ use the assumed uniform global stability, and for $t \geq \tau_\infty(x_0, u)$ use the definition of $\tau_\infty(x_0, u)$ and the continuity of $\varphi(\cdot, x_0, u)$.) In view of (3.13) and (3.14) we are almost done – except that $\beta_0(x_0, u, \cdot)$ is not strictly decreasing and not continuous. We therefore choose $\beta(x_0, u, \cdot) \in \mathcal{L}$ such that

$$\beta_0(x_0, u, t) \leq \beta(x_0, u, t) \leq 2\underline{\sigma}(\|x_0\|) \quad (t \in \mathbb{R}_0^+). \quad (3.15)$$

(Simply interpolate linearly between the points $(0, 2\underline{\sigma}(\|x_0\|))$ and $(\tau_\infty(x_0, u), \underline{\sigma}(\|x_0\|))$ and exponentially between the points $(\tau_\infty(x_0, u), \underline{\sigma}(\|x_0\|))$ and $(\infty, 0)$.) Combining (3.14) and (3.15) we finally obtain (3.1) and (3.2), which concludes the proof of the implication from (ii) to (iii) in the case where $\|\varphi(\cdot, x_0, u)\|$ eventually lies below $\gamma(\|u\|_{\mathcal{U}})$.

Suppose now that we are in the case where $\|\varphi(\cdot, x_0, u)\|$ does not eventually lie below $\gamma(\|u\|_{\mathcal{U}})$. In this case, there exists a unique $k(x_0, u) \in \mathbb{N}$ such that

$$\frac{\underline{\sigma}(\|x_0\|)}{k(x_0, u) + 1} + \gamma(\|u\|_{\mathcal{U}}) < \sup_{t \in \mathbb{R}_0^+} \|\varphi(t, x_0, u)\| \leq \frac{\underline{\sigma}(\|x_0\|)}{k(x_0, u)} + \gamma(\|u\|_{\mathcal{U}}) \quad (3.16)$$

(use the assumed uniform global stability). Set now

$$\beta_0(x_0, u, t) := \sum_{n=0}^{\infty} \frac{\underline{\sigma}(\|x_0\|)}{k(x_0, u) + n} \chi_{[\tau_n(x_0, u), \tau_{n+1}(x_0, u))}(t) \quad (t \in \mathbb{R}_0^+), \quad (3.17)$$

where

$$\begin{aligned} \tau_0(x_0, u) &:= 0 \quad \text{and} \quad \tau_n(x_0, u) := \sup M_n(x_0, u) \\ M_n(x_0, u) &:= \left\{ t \in \mathbb{R}_0^+ : \|\varphi(t, x_0, u)\| > \frac{\underline{\sigma}(\|x_0\|)}{k(x_0, u) + n} + \gamma(\|u\|_{\mathcal{U}}) \right\} \end{aligned}$$

for $n \in \mathbb{N}$. We then have

$$0 < \tau_n(x_0, u) < \infty \quad (n \in \mathbb{N}) \quad (3.18)$$

$$\|\varphi(t, x_0, u)\| \leq \frac{\underline{\sigma}(\|x_0\|)}{k(x_0, u) + n} + \gamma(\|u\|_{\mathcal{U}}) \quad (t \geq \tau_n(x_0, u) \text{ and } n \in \mathbb{N}_0) \quad (3.19)$$

$$\tau_n(x_0, u) < \tau_{n+1}(x_0, u) \quad (n \in \mathbb{N}_0) \quad \text{and} \quad \tau_n(x_0, u) \longrightarrow \infty \quad (n \rightarrow \infty). \quad (3.20)$$

(In order to see (3.18), notice that $M_n(x_0, u)$ is bounded by the assumed weak asymptotic gain property and that $\emptyset \neq M_n(x_0, u) \neq \{0\}$ by (3.16) and by the continuity of $\varphi(\cdot, x_0, u)$. In order to see (3.19) for $n = 0$, just use (3.16) – and to see it for $n \in \mathbb{N}$ use the definition of $\tau_n(x_0, u)$ and the continuity of $\varphi(\cdot, x_0, u)$. In order to see (3.20.a) for $n = 0$, just recall (3.18) – and to see it for $n \in \mathbb{N}$ notice first that $M_n(x_0, u) \subset M_{n+1}(x_0, u)$ and second that

$$\|\varphi(t, x_0, u)\| \Big|_{t=\tau_n(x_0, u)} = \frac{\underline{\sigma}(\|x_0\|)}{k(x_0, u) + n} + \gamma(\|u\|_{\mathcal{U}}) \quad (3.21)$$

by virtue of (3.19) and the continuity of $\varphi(\cdot, x_0, u)$. Consequently, $\tau_n(x_0, u) \leq \tau_{n+1}(x_0, u)$ and $\tau_n(x_0, u) \neq \tau_{n+1}(x_0, u)$ because otherwise (3.21) would imply that $\underline{\sigma}(\|x_0\|) = 0$. Contradiction to (3.9)! And finally to see (3.20.b), recall that $\|\varphi(\cdot, x_0, u)\|$ does not eventually lie below $\gamma(\|u\|_{\mathcal{U}})$. So, for every t_0 there exists a $t \geq t_0$ such that $\|\varphi(t, x_0, u)\| > \gamma(\|u\|_{\mathcal{U}})$ and therefore there also exists an $n_0 \in \mathbb{N}$ such that

$$\|\varphi(t, x_0, u)\| > \frac{\underline{\sigma}(\|x_0\|)}{k(x_0, u) + n_0} + \gamma(\|u\|_{\mathcal{U}}).$$

It thus follows that $\tau_n(x_0, u) \geq \tau_{n_0}(x_0, u) \geq t \geq t_0$ for all $n \geq n_0$, which proves the claimed convergence (3.20.b) because t_0 was arbitrary.) With the help of (3.18), (3.19), (3.20) it follows that $\beta_0(x_0, u, \cdot)$ is a monotonically decreasing step function satisfying

$$\beta_0(x_0, u, t) \longrightarrow 0 \quad (t \rightarrow \infty) \quad (3.22)$$

as well as

$$\|\varphi(t, x_0, u)\| \leq \beta_0(x_0, u, t) + \gamma(\|u\|_{\mathcal{U}}) \quad \text{and} \quad \beta_0(x_0, u, t) \leq \underline{\sigma}(\|x_0\|) \quad (3.23)$$

for all $t \in \mathbb{R}_0^+$. (Indeed, for every $t \in \mathbb{R}_0^+$ there exists by (3.20) a unique $n \in \mathbb{N}_0$ such that $t \in [\tau_n(x_0, u), \tau_{n+1}(x_0, u))$ and therefore

$$\beta_0(x_0, u, t) = \frac{\underline{\sigma}(\|x_0\|)}{k(x_0, u) + n}.$$

So, (3.22) follows by virtue of (3.20.b) while (3.23.a) follows by virtue of (3.19).) We can now choose $\beta(x_0, u, \cdot) \in \mathcal{L}$ such that

$$\beta_0(x_0, u, t) \leq \beta(x_0, u, t) \leq 2\underline{\sigma}(\|x_0\|) \quad (t \in \mathbb{R}_0^+). \quad (3.24)$$

(Simply interpolate linearly between the points $(0, 2\underline{\sigma}(\|x_0\|)$, $(\tau_1(x_0, u), \underline{\sigma}(\|x_0\|)/k(x_0, u))$, $(\tau_2(x_0, u), \underline{\sigma}(\|x_0\|)/(k(x_0, u) + 1))$, \dots). Combining (3.23) and (3.24) we finally obtain (3.1) and (3.2), which concludes the proof of the implication from (ii) to (iii) in the case where $\|\varphi(\cdot, x_0, u)\|$ does not eventually lie below $\gamma(\|u\|_{\mathcal{U}})$.

We finally show the implication from (iii) to (i). So assume that (iii) is satisfied and let $\sigma, \gamma \in \mathcal{K}$ and β be as in (iii). Combining (3.1) and (3.2) we immediately see that \mathfrak{S} is uniformly globally stable and it remains to show that it also has the weak limit

property. Set $\bar{\gamma} := \gamma \in \mathcal{K}$ and let $\varepsilon > 0$ and $(x_0, u) \in X \times \mathcal{U}$ be given. Choose a time $\bar{\tau}(\varepsilon, x_0, u) \in \mathbb{R}_0^+$ so large that

$$\beta(x_0, u, t) \leq \varepsilon \quad (t \geq \bar{\tau}(\varepsilon, x_0, u)). \quad (3.25)$$

(Such a time $\bar{\tau}(\varepsilon, x_0, u)$ exists, for if $x_0 \neq 0$ then $\beta(x_0, u, \cdot) \in \mathcal{L}$ by assumption and if $x_0 = 0$ then $\beta(x_0, u, \cdot) = 0$ by (3.2).) It then follows by (3.1) that

$$\|\varphi(t, x_0, u)\| \leq \varepsilon + \bar{\gamma}(\|u\|_{\mathcal{U}}) \quad (3.26)$$

for all $t \geq \bar{\tau}(\varepsilon, x_0, u)$. Consequently, \mathfrak{S} has the weak limit (and also the weak asymptotic gain) property, as desired. \blacksquare

4 Weak input-to-state stability and its relation to strong input-to-state stability

4.1 A counterexample

With the following example, we show that weak input-to-state stability is, in general, strictly weaker than strong input-to-state stability. We use modulated-linear systems with suitable input spaces $\mathcal{U} \subsetneq L^p(\mathbb{R}_0^+, \mathbb{R})$ to show this. Such modulated-linear systems correspond to evolution equations of the form (1.3).

Example 4.1. Choose and fix a $p \in [1, \infty) \cup \{\infty\}$ and a function $\alpha : \mathbb{R} \rightarrow \mathbb{R}_0^+$ with $\alpha(0) = 0$ such that the set

$$\mathcal{U} := \left\{ u \in L^p(\mathbb{R}_0^+, \mathbb{R}) : \alpha \circ u \text{ is locally integrable but } \int_0^\infty \alpha(u(s)) \, ds = \infty \right\} \quad (4.1)$$

is non-empty and endow \mathcal{U} with the norm $\|\cdot\|_{\mathcal{U}} := \|\cdot\|_p$. (Simple choices for such a function are, for instance, $\alpha(r) := |r|$ in case $p \neq 1$ and $\alpha(r) := |r|^{1/2}$ in case $p = 1$.) Also, let A be the generator of a strongly stable semigroup on a Banach space X and define

$$\varphi(t, x_0, u) := e^{A(\int_0^t \alpha(u(s)) \, ds)} x_0 \quad ((t, x_0, u) \in \mathbb{R}_0^+ \times X \times \mathcal{U}). \quad (4.2)$$

We now show that $\mathfrak{S} := (X, \mathcal{U}, \varphi)$ is a weakly but not strongly input-to-state stable system. In particular, we see that the implications stated as open questions in the very last paragraph of [12] do not hold true in general. It is elementary to check that \mathcal{U} is invariant under shifts to the left and under concatenations. It is also elementary to check that $\varphi(\cdot, x_0, u)$ is continuous for every $(x_0, u) \in X \times \mathcal{U}$ and that φ is cocyclic and causal. So, in other words, \mathfrak{S} is a dynamical system with inputs. Since $e^{A\cdot}$ is strongly stable, it follows that

$$M := \sup_{v \in \mathbb{R}_0^+} \|e^{Av}\| < \infty \quad (4.3)$$

by the uniform boundedness principle, and therefore \mathfrak{S} is uniformly globally stable with $\underline{\sigma}(r) := Mr$ and $\underline{\gamma} \in \mathcal{K}$ arbitrary. Since $e^{A \cdot}$ is strongly stable and since

$$\int_0^t \alpha(u(s)) \, ds \longrightarrow \infty \quad (t \rightarrow \infty) \quad (4.4)$$

for every $u \in \mathcal{U}$, it further follows that \mathfrak{S} is of weak asymptotic gain 0. So, we see that \mathfrak{S} is weakly input-to-state stable and it remains to show that it is not of strong asymptotic gain. Seeking a contradiction, assume that \mathfrak{S} is of strong asymptotic gain $\bar{\gamma}$ with corresponding times $\bar{\tau}(\varepsilon, x_0)$. Choose now an arbitrary $u_0 \in \mathcal{U}$ (non-empty!), let $\varepsilon := 1$, and choose $x_0 \in X$ such that

$$\|x_0\| > \varepsilon + \bar{\gamma}(\|u_0\|_{\mathcal{U}}). \quad (4.5)$$

Also, define $\bar{\tau} := \bar{\tau}(\varepsilon, x_0)$ and $u := 0 \&_{\bar{\tau}} u_0$. Clearly, $u \in \mathcal{U}$ and

$$\|u\|_{\mathcal{U}} = \|u_0\|_{\mathcal{U}} \quad \text{and} \quad u|_{[0, \bar{\tau}]} = 0. \quad (4.6)$$

So, by the assumed asymptotic strong gain property combined with (4.5), (4.6) and $\alpha(0) = 0$, we get that

$$\varepsilon + \bar{\gamma}(\|u\|_{\mathcal{U}}) < \|x_0\| = \left\| e^{A(\int_0^{\bar{\tau}} \alpha(u(s)) \, ds)} x_0 \right\| = \|\varphi(\bar{\tau}, x_0, u)\| \leq \varepsilon + \bar{\gamma}(\|u\|_{\mathcal{U}}). \quad (4.7)$$

Contradiction! \blacktriangleleft

4.2 Some positive results

While weak and strong input-to-state stability are inequivalent for modulated-linear systems with general input spaces \mathcal{U} , they coincide for modulated-linear systems with input space $\mathcal{U} = L^p(\mathbb{R}_0^+, U)$.

Proposition 4.2. *Suppose X is a Banach space and $\mathcal{U} := L^p(\mathbb{R}_0^+, \mathbb{R})$ for some $p \in [1, \infty) \cup \{\infty\}$. Suppose further that A is a semigroup generator on X and $\alpha : \mathbb{R} \rightarrow \mathbb{R}_0^+$ is a continuous function such that $\alpha \circ u$ is locally integrable for every $u \in \mathcal{U}$ (for example $\alpha(r) := |r|$). Then $\mathfrak{S} := (X, \mathcal{U}, \varphi)$ with*

$$\varphi(t, x_0, u) := e^{A(\int_0^t \alpha(u(s)) \, ds)} x_0 \quad ((t, x_0, u) \in \mathbb{R}_0^+ \times X \times \mathcal{U})$$

is a dynamical system with inputs and \mathfrak{S} is weakly input-to-state stable if and only if it is strongly input-to-state stable.

Proof. It is easily verified that \mathfrak{S} is a dynamical system with inputs. Also, one of the claimed implications is trivial. So, suppose that \mathfrak{S} is weakly input-to-state stable. We have to show that \mathfrak{S} is also of strong asymptotic gain and thus strongly input-to-state stable.

As a first step, we show that $\alpha(0) > 0$ in case $p < \infty$ and that $\alpha(r) > 0$ for every $r \in \mathbb{R}$ in case $p = \infty$. Seeking a contradiction, we assume that there is a constant function $u_r \equiv r \in L^p(\mathbb{R}_0^+, \mathbb{R}) = \mathcal{U}$ such that $\alpha(r) = 0$. We then have

$$\varphi(t, x_0, u_r) = e^{A(\int_0^t \alpha(u_r(s)) ds)} x_0 = x_0 \quad (t \geq 0) \quad (4.8)$$

for every $x_0 \in X$. Since \mathfrak{S} is of weak asymptotic gain $\bar{\gamma}$, say, we also have that

$$\|\varphi(t, x_0, u_r)\| \leq \varepsilon + \bar{\gamma}(\|u_r\|_{\mathcal{U}}) \quad (t \geq \bar{\tau}(\varepsilon, x_0, u_r)) \quad (4.9)$$

for every $\varepsilon > 0$ and every $x_0 \in X$. Choosing now $x_0 \in X$ such that $\|x_0\|/2 > \bar{\gamma}(\|u_r\|_{\mathcal{U}})$ and letting $\varepsilon := \|x_0\|/2$, we obtain a contradiction by combining (4.8) and (4.9).

As a second step, we observe that the semigroup $e^{A \cdot}$ is strongly stable. Indeed, since \mathfrak{S} is of weak asymptotic gain, we see by choosing $u := 0 \in \mathcal{U}$ that

$$e^{A(\alpha(0)t)} x_0 = \varphi(t, x_0, 0) \longrightarrow 0 \quad (t \rightarrow \infty) \quad (4.10)$$

for every $x_0 \in X$. Since $\alpha(0) > 0$ by the first step, the claimed strong stability follows.

As a third step, we show that for every $\bar{v}, \bar{r} \in \mathbb{R}_0^+$ there exists a time $\bar{\tau} = \bar{\tau}_{\bar{v}, \bar{r}} \in \mathbb{R}_0^+$ such that

$$\int_0^{\bar{\tau}} \alpha(u(s)) ds \geq \bar{v} \quad (u \in \mathcal{U} \text{ with } \|u\|_{\mathcal{U}} \leq \bar{r}). \quad (4.11)$$

So let $\bar{v}, \bar{r} \in \mathbb{R}_0^+$ be given and fixed. In case $p < \infty$, we know by the first step and the continuity of α that

$$c_\delta := \inf_{|r| \leq \delta} \alpha(r) > 0$$

for some $\delta > 0$. Setting $\bar{\tau} = \bar{\tau}_{\bar{v}, \bar{r}} := \bar{v}/c_\delta + \bar{r}^p/\delta^p$ and writing

$$J_{>\delta}^u := \{s \in [0, \bar{\tau}] : |u(s)| > \delta\} \quad \text{and} \quad J_{\leq \delta}^u := \{s \in [0, \bar{\tau}] : |u(s)| \leq \delta\}$$

for $u \in \mathcal{U}$, we see for every $u \in \mathcal{U}$ with $\|u\|_{\mathcal{U}} \leq \bar{r}$ that

$$\lambda(J_{>\delta}^u) \leq 1/\delta^p \int_0^{\bar{\tau}} |u(s)|^p ds \leq \bar{r}^p/\delta^p$$

and therefore

$$\int_0^{\bar{\tau}} \alpha(u(s)) ds \geq \int_{J_{\leq \delta}^u} \alpha(u(s)) ds \geq c_\delta \lambda(J_{\leq \delta}^u) = c_\delta (\bar{\tau} - \lambda(J_{>\delta}^u)) \geq c_\delta (\bar{\tau} - \bar{r}^p/\delta^p) = \bar{v},$$

which proves (4.11) in the case $p < \infty$. In case $p = \infty$, we know by the first step and the continuity of α that

$$c_{\bar{r}} := \inf_{|r| \leq \bar{r}} \alpha(r) > 0.$$

Setting $\bar{\tau} = \bar{\tau}_{\bar{v}, \bar{r}} := \bar{v}/c_{\bar{\tau}}$, we see for every $u \in \mathcal{U}$ with $\|u\|_{\mathcal{U}} \leq \bar{r}$ that

$$\int_0^{\bar{\tau}} \alpha(u(s)) \, ds \geq c_{\bar{\tau}} \bar{\tau} = \bar{v},$$

which proves (4.11) in the case $p < \infty$.

As a fourth and last step, we finally show that \mathfrak{S} is of strong asymptotic gain. Since $e^{A \cdot}$ is strongly stable by the second step, we have that

$$M := \sup_{v \in \mathbb{R}_0^+} \|e^{Av}\| < \infty \quad (4.12)$$

by the uniform boundedness principle and, moreover, we have that for every $\varepsilon > 0$ and $x_0 \in X$ there is a $\bar{v}(\varepsilon, x_0) \in \mathbb{R}_0^+$ such that

$$\|e^{Av} x_0\| \leq \varepsilon \quad (v \geq \bar{v}(\varepsilon, x_0)). \quad (4.13)$$

Set now $\bar{\gamma}(r) := Mr$ for $r \in \mathbb{R}_0^+$, let $\varepsilon > 0$ and $x_0 \in X$ be given and fixed, and define

$$\bar{\tau}(\varepsilon, x_0) := \bar{\tau}_{\bar{v}(\varepsilon, x_0), \|x_0\|}, \quad (4.14)$$

where $\bar{\tau}_{\bar{v}, \bar{r}}$ is chosen as in the third step. It then follows by (4.11), (4.13) and (4.14) that for every $u \in \mathcal{U}$ with $\|u\|_{\mathcal{U}} \leq \|x_0\|$

$$\|\varphi(t, x_0, u)\| = \left\| e^{A(\int_0^t \alpha(u(s)) \, ds)} x_0 \right\| \leq \varepsilon \leq \varepsilon + \bar{\gamma}(\|u\|_{\mathcal{U}}) \quad (4.15)$$

for all $t \geq \bar{\tau}(\varepsilon, x_0)$. It also follows by (4.12) that for every $u \in \mathcal{U}$ with $\|u\|_{\mathcal{U}} > \|x_0\|$

$$\|\varphi(t, x_0, u)\| = \left\| e^{A(\int_0^t \alpha(u(s)) \, ds)} x_0 \right\| \leq M \|u\|_{\mathcal{U}} \leq \varepsilon + \bar{\gamma}(\|u\|_{\mathcal{U}}) \quad (4.16)$$

for all $t \geq 0$. So, taking (4.15) and (4.16) together we see that \mathfrak{S} is of strong asymptotic gain $\bar{\gamma}$, as desired. \blacksquare

Similarly, weak and strong input-to-state stability coincide for linear systems with input space $\mathcal{U} = L^p(\mathbb{R}_0^+, U)$.

Proposition 4.3. *Suppose X, U are Banach spaces and $\mathcal{U} := L^p(\mathbb{R}_0^+, U)$ for some $p \in [1, \infty) \cup \{\infty\}$. Suppose further that A is a semigroup generator on X and that $B \in L(U, X_{-1})$ is a \mathcal{U} -admissible control operator for A , that is,*

$$\Phi_t(u) := \int_0^t e^{A_{-1}(t-s)} B u(s) \, ds \in X \quad (t \in \mathbb{R}_0^+ \text{ and } u \in \mathcal{U}), \quad (4.17)$$

where A_{-1} is the generator of the extrapolation of the semigroup $e^{A \cdot}$ to the extrapolation space X_{-1} of A . In case $p = \infty$ additionally assume that $t \mapsto \Phi_t(u) \in X$ is continuous for every $u \in \mathcal{U}$. Then $\mathfrak{S} := (X, \mathcal{U}, \varphi)$ with

$$\varphi(t, x_0, u) := e^{At} x_0 + \int_0^t e^{A_{-1}(t-s)} B u(s) \, ds \quad ((t, x_0, u) \in \mathbb{R}_0^+ \times X \times \mathcal{U})$$

is a dynamical system with inputs and \mathfrak{S} is weakly input-to-state stable if and only if it is strongly input-to-state stable.

Proof. Since B is \mathcal{U} -admissible for A , it follows that $\varphi(\cdot, x_0, u)$ is a continuous function from \mathbb{R}_0^+ to X by virtue of Proposition 2.3 of [22]. (It should be noted here that because of (4.17) the linear operator $\Phi_t : \mathcal{U} \rightarrow X$ is closed and thus bounded, whence the aforementioned proposition from [22] is applicable.) Also, it is clear that φ is cocyclic and causal. So, \mathfrak{S} is a dynamical system with inputs. It remains to show that if \mathfrak{S} is weakly input-to-state stable, then it is of strong asymptotic gain and hence strongly input-to-state stable (the other implication being trivial). So, let \mathfrak{S} be uniformly globally stable (with corresponding functions $\underline{\sigma}, \underline{\gamma}$) and of weak asymptotic gain $\overline{\gamma}$ (with corresponding times $\overline{\tau}(\varepsilon, x_0, u)$). Also, let $\varepsilon > 0$ and $x_0 \in X$. We then have for every $t \geq \overline{\tau}(\varepsilon, x_0, 0)$ and every $u \in \mathcal{U}$ that

$$\begin{aligned} \|\varphi(t, x_0, u)\| &\leq \|e^{At}x_0\| + \|\Phi_t(u)\| = \|\varphi(t, x_0, 0)\| + \|\varphi(t, 0, u)\| \\ &\leq \varepsilon + \overline{\gamma}(0) + \underline{\sigma}(0) + \underline{\gamma}(\|u\|_{\mathcal{U}}) = \varepsilon + \underline{\gamma}(\|u\|_{\mathcal{U}}). \end{aligned}$$

In particular, \mathfrak{S} is of strong asymptotic gain $\underline{\gamma}$, as desired. \blacksquare

Clearly, every bounded control operator $B \in L(U, X)$ is \mathcal{U} -admissible for A . Sufficient conditions for unbounded control operators $B \in L(U, X_{-1})$ to be \mathcal{U} -admissible for A can be found in [4], [21], for instance. A sufficient conditions for the continuity of $t \mapsto \Phi_t(u) \in X$ in the case $p = \infty$ is that X be a Hilbert space, U be finite-dimensional and that A generate an exponentially stable analytic semigroup on X that is similar to a contraction semigroup (Theorem 1 of [6]).

4.3 Weak input-to-state stability for semilinear systems

While for linear systems weak and strong input-to-state stability are equivalent, this is open for semilinear systems. With the next example, we show at least, however, that for such semilinear systems weak input-to-state stability is strictly weaker than uniform input-to-state stability.

Example 4.4. Suppose X, U are Hilbert spaces and $\mathcal{U} := L^2(\mathbb{R}_0^+, U)$. Suppose further that A is a contraction semigroup generator on X and $B \in L(U, X) \setminus \{0\}$ is such that $A - BB^*$ generates a strongly but not exponentially stable semigroup, and let

$$f(x) := -Bg(B^*x) \quad (x \in X),$$

where $g : U \rightarrow U$ is Lipschitz continuous on bounded subsets and

$$g(v) = v \quad (\|v\| \leq 1) \quad \text{and} \quad \langle v, g(v) \rangle \geq c \quad (\|v\| > 1) \quad (4.18)$$

for some positive constant $c > 0$. (Simple choices for such operators are given by self-adjoint operators A with $\sigma(A) \subset (-\infty, 0]$ and with 0 belonging to the essential but not to the point spectrum of A and by compact operators $B \in L(U, X)$ such that BB^* commutes with A . Another possible choice of operators A and B as above is given by Example 3.2 of [18].) It then follows from [19] (similarly to [1]) that for every $(x_0, u) \in X \times \mathcal{U}$ the initial value problem

$$x' = Ax + f(x) + Bu(t) \quad \text{and} \quad x(0) = x_0$$

has a unique global mild solution $\varphi(\cdot, x_0, u) \in C(\mathbb{R}_0^+, X)$ and that for $(x_0, u) \in D(A) \times C_c^1(\mathbb{R}_0^+, U)$ this mild solution is even a classical solution. It also follows from [19] (similarly to [1]) that $\mathfrak{S} := (X, \mathcal{U}, \varphi)$ is a weakly input-to-state stable dynamical system with inputs. We now show that the system \mathfrak{S} is not uniformly input-to-state stable. Assume the contrary and set $r := \underline{\sigma}^{-1}(1/\|B\|)$. We then have for every $x_0 \in D(A)$ with $\|x_0\| \leq r$ that $\|B^*\varphi(t, x_0, 0)\| \leq 1$ for all $t \in \mathbb{R}_0^+$ by the uniform global stability of \mathfrak{S} and therefore

$$\varphi(t, x_0, 0) = e^{(A-BB^*)t}x_0 \quad (t \in \mathbb{R}_0^+) \quad (4.19)$$

by (4.18) and the classical solution property of $\varphi(\cdot, x_0, 0)$. Since now \mathfrak{S} is of uniform asymptotic gain by our assumption, it follows that

$$r \left\| e^{(A-BB^*)t} \right\| = \sup \{ \|\varphi(t, x_0, 0)\| : x_0 \in D(A) \text{ with } \|x_0\| \leq r \} \longrightarrow 0 \quad (4.20)$$

as $t \rightarrow \infty$. Consequently, $e^{(A-BB^*)\cdot}$ is exponentially stable. Contradiction (to our choice of A and B)! \blacktriangleleft

5 Weak input-to-state stability and its relation to zero-input uniform global stability

5.1 A counterexample

With the following example, we show that weak input-to-state stability is, in general, strictly stronger than the combination of zero-input uniform global stability and the weak asymptotic gain property. We use linear systems with a suitable input space $\mathcal{U} \subsetneq L^\infty(\mathbb{R}_0^+, \mathbb{R})$ to show this.

Example 5.1. Set $X := L^2(\mathbb{R}_0^+, \mathbb{R})$ and

$$\mathcal{U} := \{u \in L^\infty(\mathbb{R}_0^+, \mathbb{R}) : u \text{ is eventually exponentially decaying to } 0\} \quad (5.1)$$

and endow \mathcal{U} with the norm $\|\cdot\|_{\mathcal{U}} := \|\cdot\|_\infty$. (What we mean by a function u that eventually exponentially decays to 0 is that there exists a time $\tau_u \in \mathbb{R}_0^+$ and constants $C_u, \alpha_u > 0$ such that $|u(s)| \leq C_u e^{-\alpha_u s}$ for all $s \geq \tau_u$.) Also, let A be the generator of the left-translation group on X , that is,

$$e^{At}f = f(\cdot + t) \quad (f \in X \text{ and } t \in \mathbb{R}_0^+),$$

and let $B \in L(\mathbb{R}, X)$ be given by $Bv := vb$ for $v \in \mathbb{R}$, where $b \in X$ is chosen such that

$$b(\zeta) \geq 0 \quad (\zeta \in \mathbb{R}_0^+) \quad \text{and} \quad b \notin L^1(\mathbb{R}_0^+, \mathbb{R}) \quad (5.2)$$

(for example, $b(\zeta) = 1/\zeta \chi_{[1, \infty)}(\zeta)$). We now show that $\mathfrak{S} := (X, \mathcal{U}, \varphi)$ with

$$\varphi(t, x_0, u) := e^{At}x_0 + \int_0^t e^{A(t-s)}Bu(s) ds \quad ((t, x_0, u) \in \mathbb{R}_0^+ \times X \times \mathcal{U}) \quad (5.3)$$

is a system (with bounded reachability sets and with continuity at the equilibrium point 0) which is zero-input uniformly globally stable and of weak asymptotic gain 0 but not uniformly locally stable. In particular, \mathfrak{S} is not weakly input-to-state stable and, moreover, we see that the second question-marked implication in Figure 2 of [12] does not hold true in general. It is elementary to check that \mathcal{U} is invariant under shifts to the left and under concatenations. Also, it is clear that $\varphi(\cdot, x_0, u)$ is continuous for every $(x_0, u) \in X \times \mathcal{U}$ and that φ is cocyclic and causal. So, in other words, \mathfrak{S} is a dynamical system with inputs. Since $e^{A\cdot}$ is a contraction semigroup, it follows that \mathfrak{S} is zero-input uniformly globally stable. It also follows that \mathfrak{S} has bounded reachability sets and is continuous at the equilibrium point 0 (Definition 3 and 4 of [12]). Since $e^{A\cdot}$ is strongly stable and every $u \in \mathcal{U}$ is eventually exponentially decaying to 0, it further follows that

$$\varphi(t, x_0, u) \longrightarrow 0 \quad (t \rightarrow \infty)$$

for every $(x_0, u) \in X \times \mathcal{U}$ or, in other words, that \mathfrak{S} is of weak asymptotic gain 0. So, what remains to be shown is that \mathfrak{S} is not uniformly locally stable. Assume, on the contrary, that \mathfrak{S} is uniformly locally stable with corresponding functions $\underline{\sigma}$, $\underline{\gamma}$ and radius r . Since $b \in X$ satisfies (5.2), we see with the help of Fatou's lemma that

$$\begin{aligned} \liminf_{t \rightarrow \infty} \left\| \int_0^t b(\cdot + s) ds \right\|^2 &= \liminf_{t \rightarrow \infty} \int_0^\infty \left(\int_0^t b(\zeta + s) ds \right)^2 d\zeta \\ &\geq \int_0^\infty \left(\int_0^\infty b(\zeta + s) ds \right)^2 d\zeta = \infty. \end{aligned}$$

In particular, there exists a time $\bar{\tau} \in \mathbb{R}_0^+$ such that

$$r \cdot \left\| \int_0^{\bar{\tau}} b(\cdot + s) ds \right\| > \underline{\gamma}(r). \quad (5.4)$$

Choose now a $u \in \mathcal{U}$ such that

$$u|_{[0, \bar{\tau}]} \equiv r \quad \text{and} \quad \|u\|_{\mathcal{U}} = r. \quad (5.5)$$

It then follows by (5.4) and (5.5) that $(0, u) \in \overline{B}_r^X(0) \times \overline{B}_r^{\mathcal{U}}(0)$ but

$$\|\varphi(\bar{\tau}, 0, u)\| = \left\| \int_0^{\bar{\tau}} u(s) \cdot e^{A(\bar{\tau}-s)} b ds \right\| = r \cdot \left\| \int_0^{\bar{\tau}} b(\cdot + s) ds \right\| > \underline{\gamma}(r) = \underline{\sigma}(0) + \underline{\gamma}(r).$$

Contradiction (to our uniform local stability assumption)! \blacktriangleleft

5.2 A positive result

While weak input-to-state stability and the combination of zero-input uniform global stability and the weak asymptotic gain property are inequivalent for linear systems with general input spaces \mathcal{U} , they coincide for linear systems with input space $\mathcal{U} = L^p(\mathbb{R}_0^+, U)$.

Proposition 5.2. *Suppose $\mathfrak{S} := (X, \mathcal{U}, \varphi)$ is as in Proposition 4.3. Then \mathfrak{S} is a dynamical system with inputs and \mathfrak{S} is weakly input-to-state stable if and only if it is zero-input uniformly locally stable and of weak asymptotic gain.*

Proof. We already know that \mathfrak{S} is a dynamical system with inputs, and one of the claimed implications is trivial. So, let \mathfrak{S} be zero-input uniformly locally stable (with corresponding function $\underline{\sigma}$ and radius r) and of weak asymptotic gain $\overline{\gamma}$ (with corresponding times $\overline{\tau}(\varepsilon, x_0, u)$). We then have

$$\begin{aligned} \|e^{At}x_0\| &= \|\varphi(t, x_0, 0)\| \leq \underline{\sigma}(\|x_0\|) & (x_0 \in \overline{B}_r^X(0) \text{ and } t \geq 0) \\ \|\Phi_t(u)\| &= \|\varphi(t, 0, u)\| \leq 1 + \overline{\gamma}(\|u\|_{\mathcal{U}}) & (u \in \overline{B}_r^{\mathcal{U}}(0) \text{ and } t \geq \overline{\tau}(1, 0, u)). \end{aligned}$$

So, by linearity and the continuity of $[0, \overline{\tau}(1, 0, u)] \ni t \mapsto \Phi_t(u)$ for $u \in \mathcal{U}$, we see that $\mathbb{R}_0^+ \ni t \mapsto e^{At}x_0 \in X$ and $\mathbb{R}_0^+ \ni t \mapsto \Phi_t(u) \in X$ are bounded functions for all $x_0 \in X$ and $u \in \mathcal{U}$ and therefore

$$M_1 := \sup_{t \in \mathbb{R}_0^+} \|e^{At}\| < \infty \quad \text{and} \quad M_2 := \sup_{t \in \mathbb{R}_0^+} \|\Phi_t\| < \infty \quad (5.6)$$

by the uniform boundedness principle. Consequently,

$$\|\varphi(t, x_0, u)\| \leq M_1 \|x_0\| + M_2 \|u\|_{\mathcal{U}} \quad (t \geq 0)$$

for every $(x_0, u) \in X \times \mathcal{U}$. In particular, \mathfrak{S} is uniformly globally stable and hence weakly input-to-state stable, as desired. \blacksquare
